### Lake of Bays Water Quality Report 2019

Prepared for: Lake of Bays Association  
Job #: J100013

February 2020

## Final Report

February 27, 2020

HESL Job #: J100013

Ms. Deb Cumming  
Environment Committee  
Lake of Bays Association  
PO Box 8  
Baysville, ON P0B 1A0

Dear Ms. Cumming:

**Re: Lake of Bays Water Quality Report 2019**

I am pleased to submit this final report for the Lake of Bays Water Quality Monitoring Program presenting the results of total phosphorus and bacteria sampling from the summer of 2019.

As in previous years, total phosphorus and bacteria levels were well below applicable Provincial guidelines indicating excellent water quality in 2019. Statistically significant trends in total phosphorus were recorded at the Deep Water stations since 2002, however our analysis suggest that these patterns are strongly correlated with natural regional precipitation patterns and in 2019 we have noted an overall decrease in TP concentrations compared to historical averages.

I thank you and the Lake of Bays Association for the continued opportunity to assist with this project.

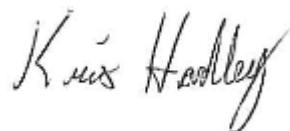

Sincerely,  
per: Hutchinson Environmental Sciences Ltd.

## Appendices

Appendix A. Monitoring Protocols for the LOBA Water Quality Monitoring Program
Appendix B. LOBA Total Phosphorus and Bacteria Data

## 1. Introduction

Since 2001, the Lake of Bays Association (LOBA) has championed a volunteer-based water quality monitoring program in Lake of Bays. The aim of the program is to characterize phosphorus and bacteria levels as an indication of general lake and watershed health and to compare different sites across the lake, while fostering community involvement and education.

Although LOBA had been monitoring spring turnover phosphorus levels as part of the Ministry of Environment, Conservation and Park's Lake Partnership Program, LOBA's independent monitoring program began with a pilot study in 2000 to monitor bacteria levels in the lake during the summer. This project was successful, deemed valuable and LOBA expanded the area of study in the summer of 2001 to include near-shore sites adjacent to developed and undeveloped properties, and areas influenced by wetlands and rivers. In 2002, the program was again expanded to include monitoring of total phosphorus concentrations in near-shore areas and in the Hollow and Oxtongue rivers and river deltas (deep water sites were already being monitored). Site selection has changed as our understanding of water quality conditions in Lake of Bays has increased and, since 2009, sampling has focused on deep water sites, nearshore disturbed and undisturbed locations, and inflowing rivers.

The LOBA monitoring program continues to focus on total phosphorus concentrations. For recreational lakes on the Precambrian Shield like Lake of Bays, water quality concerns are most often associated with nutrient enrichment due to increased human phosphorus sources. Phosphorus is a natural element in the environment and enters lakes from the atmosphere through precipitation, from streams and overland flow, and to a lesser degree through groundwater. Human sources to recreational lakes include storm water runoff and erosion from altered land uses, fertilizers on manicured lawns and faulty septic systems. Increases in phosphorus loads to lakes from human sources can result in increased growth of aquatic plants and algae, which in turn can lead to a deterioration of water clarity and coldwater fish habitat through a decrease in deep-water oxygen concentrations.

Sampling frequency for bacteria (total coliform and *Escherichia coli*) was reduced to every other year from 2009 to 2013 because earlier monitoring results were very consistent between sites and years, and similar to background levels. Previous monitoring reports have suggested that a reduction in bacteria sampling was warranted; beginning in 2016, it was recommended that bacteria sampling be conducted only in the mid-summer each year at the nearshore sites. Every five years the collection of bacteria samples on all sampling dates was recommended. The reduced sampling frequency will continue to allow assessment of long-term trends, while increasing resources the number of parameters of interest to the Association and maintaining familiarity with bacteria sampling techniques.

The program continues to demonstrate that Lake of Bays is a clear water lake with low phosphorus and bacteria levels with no obvious impact of development on water quality. In this report we present the results of the summer phosphorus monitoring completed by the LOBA in 2019 and discuss them in the context of long-term water quality data collected by the LOBA and local precipitation records.

## 2. Methods

Volunteers, coordinated by the LOBA Environment Committee, collected samples for analysis of total phosphorus on three occasions during the summer of 2019 (July 1, August 5 and 30) and on August 5 for bacteria (*E. coli* and total coliforms). The sampling and analytical methods in 2019 were consistent with those used in previous monitoring years and are summarized below. Detailed sampling instructions that are provided to the volunteers are presented in Appendix A.

### 2.1 Sample Collection

Water samples for bacteria and total phosphorus were collected at 21 sites in Lake of Bays to include deep, open water locations ('Deep Water' sites, n=9), nearshore sites adjacent to developed ('Disturbed' sites, n=3) and undeveloped shorelines ('Nearshore Undisturbed' sites, n=6), and river (Oxtongue and Hollow rivers) and river-influenced (Oxtongue Delta) sites ('River' sites, n=3) (Table 1, Figure 1). A single, new nearshore undisturbed site was included in the 2019 sampling program at the Portage Bay Docks (N31) but is not expected to become a regular part of the program.

At each Deep Water site, a composite water sample was collected from the euphotic zone, at approximately two times the Secchi depth. At all other sites, the water sample was collected at a depth of ~30 cm. Six field duplicate samples for bacteria and 15 additional duplicates for laboratory analysis were collected. In addition, seven field duplicate samples for total phosphorus were collected to assess the variability of results related to sampling and analytical procedures (Table 1).

Phosphorus samples were coarse-filtered using a filtered syringe in order to remove zooplankton (microscopic animals living in the water, such as water fleas) or other large debris that can contaminate the sample and result in non-representative, high phosphorus values (Clark et al., 2010). Samples were then directly poured into sampling containers with acid preservative, stored in a cool place and submitted for analysis to ALS Environmental Laboratory.

## 2.2 Quality Control

### 2.2.1 Bacteria

Field duplicate bacteria concentrations were compared to assess variability in the results due to sampling and analysis by the Coliplate method.

### 2.2.2 Total Phosphorus

#### 2.2.2.1 *Field Duplicates*

Duplicate samples were collected for 14 of the 53 samples. Bad splits in the LOBA dataset were identified for duplicate samples that were >35% different or had an absolute difference of >5 µg/L (Hyatt et al., 2012). If a bad split was identified, the higher of the two values was discarded.

#### 2.2.2.2 *Outliers*

In relatively small datasets like the LOBA dataset, the calculation of average total phosphorus concentration is sensitive to outliers, that is, extreme values that are not representative of the site condition. Rosner's ESD Many-Outlier Procedure (Rosner's Test; Rosner, 1983) was performed in the R statistical Software Environment V. 3.3.3, using the "rosnerTest" function of the "EnvStats" package (Millard, 2013), to identify outliers in total phosphorus concentrations collected since 2002 for each LOBA monitoring site. This procedure detects high and low extreme values and is not limited for multiple outliers.

Statistically significant outliers (at  $p<0.05$ ) were removed from the dataset for further analyses (as detailed in Section 3.1.3) but will be re-evaluated each year as additional data are collected, as outliers may, over time, indicate a change to average conditions.

#### 2.2.2.3 *Detection Limits*

Laboratory detection limits changed in 2018 (0.1 to 3 µg/L) as the result of an unavoidable laboratory change from Trent University at the Dorset Environmental Science Centre to ALS Environmental. Values below detection were substituted with the full detection limit to make the most conservative estimate of total phosphorus concentrations in the samples collected. In 2019, 28 of the 75 (37%) samples collected were below the detection limit.

## 2.3 Data Analysis

### 2.3.1 Bacteria

Bacteria (*E. coli* and total coliform) levels were compared to the Provincial Water Quality Objectives (PWQO) for recreational water use (MOEE, 1994). The former benchmark for total coliform was 1,000 colony forming units (cfu) per 100 mL, based on a geometric mean for a series of water samples and is intended as a general guideline. Bacterial assessment of water quality should be based on more specific fecal bacteria indicators such as *E. coli*. The PWQO for *E. coli* is 100 cfu per 100 mL, based on a geometric mean of at least five samples taken from one site within one month. Where testing indicates sewage or

fecal contamination, a site-specific judgment must be made as to the severity of the problem and the appropriate course of action.

### 2.3.2 Total Phosphorus

Mean total phosphorus concentrations were calculated for each site and site type for the 2019 monitoring period following the assessment of bad splits between duplicate samples and outliers.

Total phosphorus (TP) results were evaluated against the interim PWQO for phosphorus, which suggests average ice-free period TP concentrations should not exceed 20 µg/L in order to avoid nuisance algal growth and that maintaining TP concentrations at or below 10 µg/L provides protection against aesthetic deterioration (MOE 1994). Furthermore, excessive macrophyte growth in rivers and streams should be reduced below 30 µg/L of TP (MOEE, 1994).

Mann Kendall Trend analysis was performed using the “mk.test” and “sens.slope” functions of the “Trend” package in R (Pohlert, 2017) to assess any long-term changes in total phosphorus concentrations over time (2002-2018) for each site.

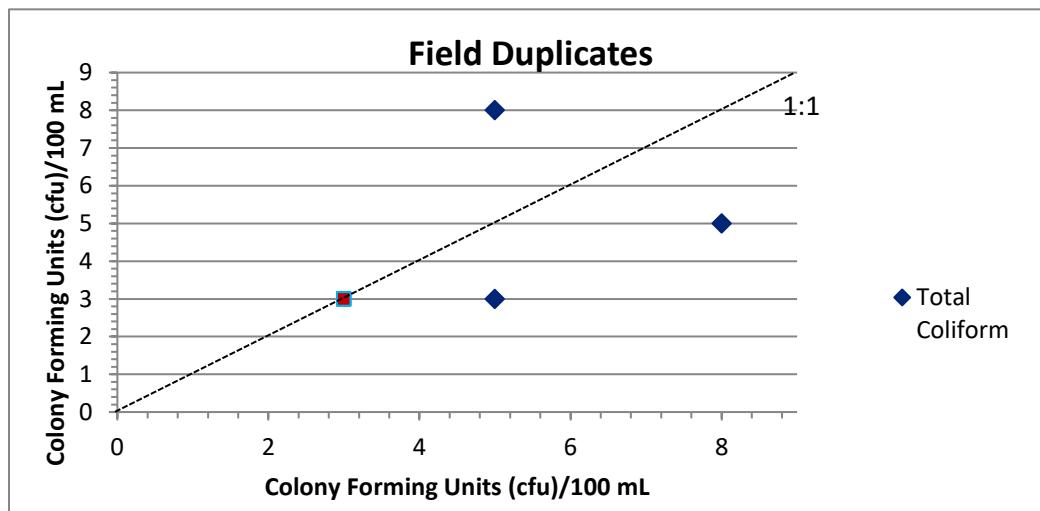

## 3. 2019 Monitoring Results

### 3.1 Quality Control

#### 3.1.1 Bacteria

The duplicate analysis of the Coliplate samples in 2019 provided a high degree of confidence in the sampling protocols and analyses for bacteria (Figure 2). The maximum differences between bacteria duplicates using the Coliplate method was 1 cfu/100 mL for *E. coli* and 30 cfu/100 mL for total coliforms. Pairwise testing of the Coliplate duplicate samples showed no significant difference ( $p<0.05$ ).

**Figure 2. Comparison of field duplicate results for total coliform and *E. coli*, 2019**

**Table 2. Summary of E. coli and Total Coliform QA/QC samples 2019**

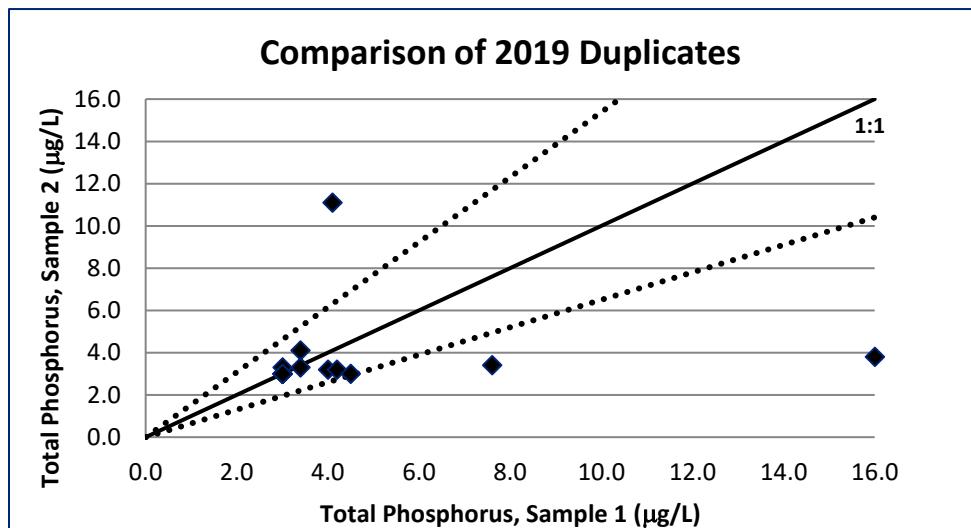

Site	E. coli Coliplate 1	E. coli Coliplate 2	Total Coliform Coliplate 1	Total Coliform Coliplate 2
	cfu/100 mL	cfu/100 mL	cfu/100 mL	cfu/100 mL
Boothby's	3	3	8	5
Gull Rock	3	3	5	8
Moffat's	3	3	3	5

### 3.1.2 Total Phosphorus

#### 3.1.2.1 Field Duplicates

In 2019, three of the field duplicates collected ( $n=14$ ) were bad splits (i.e.,  $5 \mu\text{g/L}$  or  $>35\%$  difference between sample pairs), up from 0 in 2018 (Figure 3; Table 3). By contrast, the average annual proportion of bad splits in samples since 2005, when duplicate sampling began, is 18%. The increased occurrence of bad splits in 2019 was likely a result of a decrease in the overall number of duplicates sampled (14 sites in 2018 vs 22 in pre-2017 sampling years). One of the three bad splits was also near the detection limit ( $3 \mu\text{g/L}$ ) where measurement error at the lab would be expected to increase. Continued diligent compliance to and review of sampling protocols are necessary to ensure the integrity of the data.

**Figure 3. Total phosphorus field duplicates in Lake of Bays, 2019.**

*Note: Dotted lines enclose 35% difference from the 1:1 line.*

The mean difference between field duplicates after removing the bad splits was  $0.45 \mu\text{g/L}$  in 2019, up from  $0.2 \mu\text{g/L}$  in 2018 but down from  $0.67 \mu\text{g/L}$  in all previous years (2005-2017).

**Table 3. Summary of Bad Splits between Total Phosphorus Field Duplicates in Lake of Bays, 2005-2019**

	21-Aug-17	11.1	6.1

*Note: Values in grey shaded cells were considered to be contaminated and were excluded from further analyses.*

### 3.1.3 Outliers

A total of 51 samples were identified as outliers in the LOBA dataset (excluding River sites) using the Rosner's Test, three of which occurred in the 2019 monitoring year (Table 4). Outliers and bad splits (Section 3.1.2) in 2019 suggests a reasonable rate of sampling contamination, and that the field sampling at LOBA is being performed carefully and is yielding high quality data.

**Table 4. Outliers in the LOBA Dataset (2002-2019), Rosner's Test ( $p < 0.01$ )**

With the addition of the 2019 data, no previously identified outliers were added back to the data set for statistical analyses. Outliers were removed from all analyses in this report but will be reassessed each year as additional data are added to the dataset.

### 3.2 Bacteria

Bacteria levels in Lake of Bays on August 5 were low at all Deep Water sites, with the exception of Portage Bay (3 - 5 cfu/100mL). *E. coli* concentrations were elevated at Portage Bay relative to other Deep Water sites (33 cfu/100 mL), but still well below the provincial guideline. Higher bacteria counts observed in the river-influenced (11 - 13 cfu/100mL) and nearshore sites (3 - 16 cfu/100mL) are to be expected given increased exposure to bacteria sources from wildlife and human activity, lower dilution and less time for assimilation or attenuation in comparison to the offshore Deep Water sites. Absolute bacteria counts were below the PWQO of 100 cfu/100 mL for *E. coli* and benchmark value of 1,000 cfu/100 mL for total coliform at all sampling sites (Table 5).

**Table 5. Summer E. coli and Total Coliform Concentration in Surface Water Collected by Coliplate Technique, 2019**

### 3.3 2019 Total Phosphorus Concentrations

Samples collected during the 2019 monitoring campaign were characterized by low phosphorus concentrations typical in oligotrophic, clear-water lakes on the Precambrian Shield. The summer total phosphorus concentrations of the Deep Water, Disturbed, and Nearshore Undisturbed sites ranged from 3.0 to 10.3 µg/L, with an overall mean concentration of 3.7 µg/L (Table 6). These values are similar to mean spring overturn concentrations of 3.9-6.9 µg/L measured in seven locations in Lake of Bays by the District of Muskoka's Program, which targets only deep-water sites, however DMM data are only posted for 2017. (<http://www.muskokawaterweb.ca/lake-data/muskoka-data/lake-data-sheets/lake-of-bays>).

River sampling sites were more phosphorus-enriched (mean TP = 4.6 µg/L), as would be expected given the higher concentrations of particulate matter and dissolved organic carbon typical in rivers. Mean summer

total phosphorus concentration was less than the interim PWQO for phosphorus of 10 µg/L for the lake sites and of 30 µg/L for the river sites, suggesting a low risk of aesthetic deterioration due to nuisance aquatic plant growth (MOEE, 1994).

Total phosphorus concentrations remained relatively consistent at the Deep Water, and Nearshore Undisturbed sites throughout the summer (Figure 4, Figure 5, Figure 8). We found no consistent pattern in total phosphorus concentrations for Disturbed or River sites, however data were more limited in 2019 due to missed sampling events, bad splits and outliers (Figure 6, Figure 7, Figure 8). It is likely that variability between sampling events is driven by local factors, e.g., storm events, as has been observed in previous monitoring years (HESL, 2016a). There was no significant difference (Mann-Whitney test;  $p > 0.05$ ) in phosphorus concentration between the Nearshore Undisturbed (mean TP = 3.3 µg/L) and Disturbed (mean TP = 3.4 µg/L) sites suggesting that shoreline disturbance has had little impact on summer phosphorus concentrations.

An additional site at Portage Bay (i.e. N26 – Portage Bay), initially sampled in 2012 to address concerns over potential water quality degradation following construction activities, has been maintained as a part of the LOBA sampling program. Mean total phosphorus concentration in Portage Bay ranged from 8.1 µg/L to 3.9 µg/L from 2013 to 2019, representing a decline from elevated concentrations observed in 2012 (mean TP = 9.6 µg/L) that were coincident with construction activities. The average value of 8.1 µg/l recorded at Portage Bay in 2017, was attributed to higher than average summer precipitation (442 mm) not long-term construction impacts which is supported by the lower summer precipitation (250 mm; 200 mm) and TP concentration (7.3 µg/L; 3.9 µg/L) measured in 2018 and 2019 respectively.

## 4. Long-term Phosphorus Patterns

The Lake of Bays Water Quality Monitoring Program has collected data over the summer season for 18 years at 12-21 locations throughout the lake. The yearly number of samples collected including QA/QC samples ranged from 50 in 2002 to 123 in 2012, with a total of 1,689 samples collected by the end of the 2019 program (Table 7). The large number of sites monitored, and samples collected under the program since 2002 provide for a robust data set for assessing long-term trends and inter-annual variability in total phosphorus concentration in Lake of Bays. The complete LOBA monitoring program data set since 2002 is provided in Appendix B.

Mean summer total phosphorus concentrations increased slightly in 2019 in the Deep Water (mean TP = 4.8 µg/L), but decreased in the Disturbed (mean TP = 3.4 µg/L) and Nearshore Undisturbed (mean TP = 3.3 µg/L) sites (Table 8, Figure 9) relative to 2018 values. In the past, River sites have been more variable with generally higher concentrations than lake stations, however in 2019 total phosphorus concentrations ranged from 3.0 to 7.0 µg/L, and mean TP (4.5 µg/L) was lower than the mean TP at Deep Water sites (4.8 µg/L). Water quality monitoring of rivers in 2019 was confounded by missed sampling events and an extreme outlier at Oxtongue mouth (646 µg/L) which reduced the sample size and played a role in reducing the range in values. Elevated TP at the River stations is not uncommon in the dataset and therefore we recommend the addition of total suspended solids sampling at river stations to the program to determine if river total phosphorus is associated with high sediment loads in the river or if it is the result of sample contamination. The addition of suspended solids sampling to the 2020 program will be discussed with the program administrator and Environment Committee.

The statistically significant increasing trend in mean summer total phosphorus concentration of the Deep Water sites identified in previous reports was no longer significant with the addition of data collected in 2019 (Figure 10; Mann Kendall Trend Test:  $p>0.05$ , Sen's Slope = 0.05), nor were previously identified significant increasing trends at one of the two individual Deep Water sites (i.e., Fairview and Trading Bay; Figure 11). Significant increasing trends in TP at Trading Bay, however, were still detected after the addition of the 2019 data, however average yearly change was low (0.019 µg/L/yr);

Figure 12). No other significant increases in total phosphorus concentrations were detected in any LOBA monitoring station. The average increase in total phosphorus concentration for Deep Water sites (2002 – 2019) was 0.05 µg/yr, representing a total increase of 19% or 0.9 µg/L over 18 years (based on the Sen's Slope of 0.05). This degree of change no longer exceeds what would be expected due to natural year to year variability for low productivity lakes on the Precambrian Shield, which have been found to vary naturally by an average of 21-23% between years (Clark et al., 2010).

**Figure 12. Long-term Total Phosphorus Concentrations at the Trading Bay Station**

Long-term monitoring has shown increasing trends in total phosphorus have occurred in some Muskoka lakes monitored by the Dorset Environmental Science Centre (DESC), while other lakes exhibited decreasing or no trends (Andrew Paterson, MOECC lake scientist, pers. comm.). These lakes had little to no development in their watersheds and so regional (e.g., climate change, long range atmospheric deposition) and local factors other than development may be influencing lakes in the Muskoka area, including Lake of Bays. The District of Muskoka (DMM) has monitored spring total phosphorus at deep water sites in Lake of Bays since 2001 and has observed no increase, suggesting that the patterns seen in the LOBA data set may be related to sampling later in the summer (HESL 2016b).

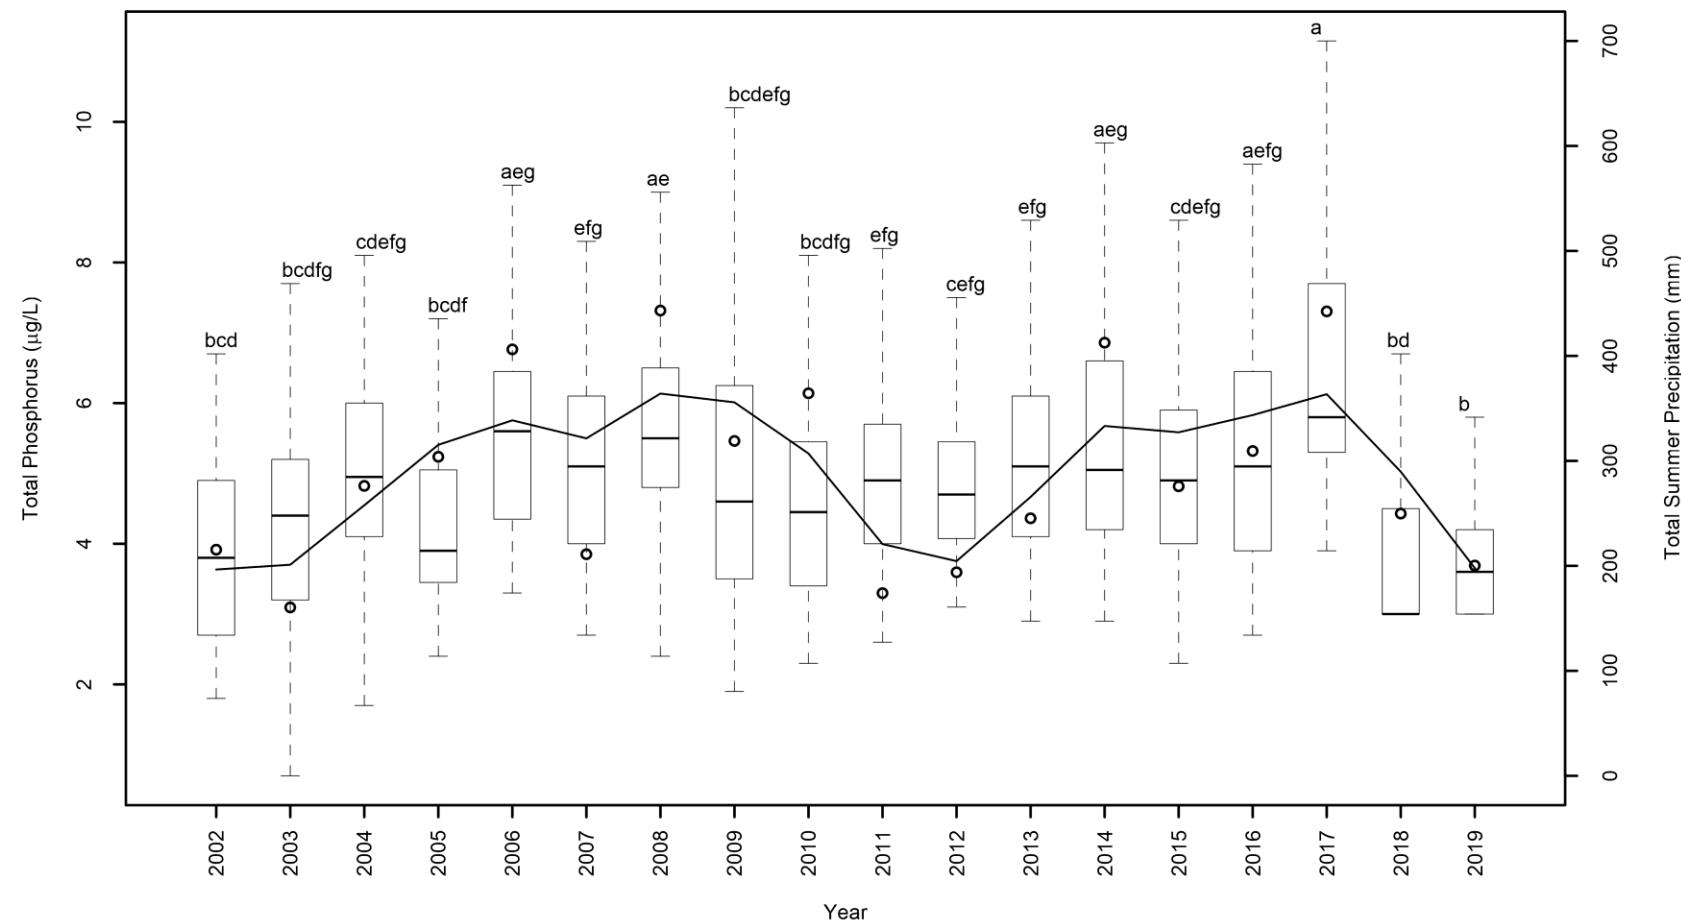

Changes in annual precipitation patterns (amount of precipitation, frequency and duration of storm events) can strongly influence phosphorus loads from atmospheric deposition and also the mobilization and transport of phosphorus from the watershed. Long-term data collected in Lake of Bays, coupled with climate data from Beatrice Climate Station, suggests that inter-annual variability in precipitation may exert a significant influence on the total phosphorus concentration in the lake (Figure 13). In general, total phosphorus concentrations tended to decrease in drier years over the period of record. Lower total phosphorus concentrations in 2019 were statistically similar to those recorded in 2002, 2003, 2005, 2009, 2010, 2018 and significantly lower than all the other years on record (Figure 13, similarity indicated by the letter "b").

The relationship identified by HESL in 2016 between mean annual summer phosphorus concentrations and total summer precipitation at Haystack Bay continues to be apparent when including 2019 data and is significant when assessing the Deep Water average as well (Haystack: Pearson rho = 0.51, n = 17,  $p < 0.05$ ; Deep Water sites: 0.61, n=18,  $p < 0.05$ ; Figure 14). We first tested the impact of precipitation of total phosphorus values in Lake of Bays in Haystack Bay because it is an isolated bay which has a large surface area ( $4.94 \text{ km}^2$ ) relative to the area of its watershed ( $8.13 \text{ km}^2$ ) and does not receive any significant river or stream discharge and thus direct phosphorus loads from local runoff and direct precipitation likely contribute to a large portion of the natural phosphorus load making it especially sensitive to changes in precipitation volume and storm severity. Phosphorus loading estimates by the DMM indicated that the total load from precipitation constitutes 49% of the natural load to Haystack Bay in comparison to 28% for the main basin of the lake (GLL, 2005). The evidence of a significant influence of regional precipitation on TP concentrations in Lake of Bays is now more broadly apparent across Nearshore and Deep Water stations.

In summary, summer total phosphorus concentration in Lake of Bays exhibits significant inter-annual variability, which based on long-term TP and precipitation data appears to be driven by natural processes related to precipitation. The Lake of Bays Association water quality monitoring program continues to provide a robust long-term data set to evaluate changes over time.

Note: Deep Water sites exclude Little Trading Bay and Portage Bay

## 5. Summary

The total phosphorus and bacteria data collected by the LOBA in 2019 indicated low nutrients and bacteria concentrations at all sampling sites in the Lake of Bays. The main results of data analyses from 2019 are as follows:

1. The LOBA monitoring program continued to provide high quality phosphorus data, although this year saw a small increase in the occurrence of bad splits and outliers relative to 2018.
2. Deep Water sites no longer exhibited the significant increasing trend in total phosphorus concentration that has been identified in past reports.
3. Significant long-term trends in total phosphorus were detected in the lake at Trading Bay, however the previously identified positive trend at the Fairview Station no longer exhibited a positive trend with the addition of 2019 data.
4. Bacteria levels collected by the Coliplate technique were below the PWQO for recreational use at all sites.
5. Total phosphorus concentrations (mean TP = 3.9 µg/L excluding the River sites) continue to be characteristic of lakes with low primary productivity and meet the highest Provincial standards for protection of nuisance aquatic plant growth due to phosphorus of <10 µg/L at all sites, except for a single value of 10.3 µg/L measured at Trading Bay on July 1, 2019.
6. Mean summer total phosphorus concentration in Portage Bay has been consistently low since 2013, representing a decline from elevated concentrations observed in 2012 that coincided with construction activities. Low TP at Portage Bay in 2019 coinciding with low precipitation supports the conclusions of the 2017 and 2018 monitoring report that increased TP was a consequence of higher than average precipitation in 2017 and not long-term construction impacts.

7. As in previous monitoring, no significant difference in phosphorus concentration between the Deep Water, Disturbed and Nearshore Undisturbed sites were found, suggesting that shoreline disturbance is having little impact on summer phosphorus concentrations.
8. Our analysis suggests that changes in total phosphorus concentrations in the lake are the result of regional precipitation and not likely a result of development pressure.
9. We recommend the addition of total suspended solids sampling at River stations to help us better understand the influence of total suspended solids on total phosphorus concentrations.

## Appendix A. Monitoring Protocols for the LOBA Water Quality Monitoring Program

# WATER QUALITY SAMPLING PROCEDURES

## General:

1. Check for equipment, including:
  - metre depth pole (if required)
  - thermometer
  - cooler and ice packs
  - sterilized jars, phosphorus tubes, duplicates
  - secchi depth disc and jar (if required)
  - data sheets and pen
2. verify that you have the appropriate boating safety equipment on board and that the weather is safe for sampling
3. record air temperature on data sheet as you leave the dock. Then attach thermometer to a rope in preparation for taking water temperature at sampling sites.
4. at each site, complete the data sheet, recording any factors or conditions that may make the sampling trip unusual or that may have an influence on sample results (eg. cloudy water, unusual activity in the area, presence of waterfowl)

## Coliform and E coli testing

*Near shore sample collected 22 – 30 cm. below the surface in water that is 1 m. in depth  
Deep water samples also collected 22 – 30 cm. below the surface of the water.*

1. Carefully and correctly assemble the jars required for the specific site (all should be named and number coded)
2. Remove the cap/lid from the jar/bottle **without touching the inside of the lid or jar**, and place carefully, upside down on a flat stable surface
3. Grip the bottle at the base and plunge it into the water in a downward motion to the a depth of 22 – 30 cm. ( 9 – 15 in). The bottle goes in **upside down** (open end to lake bottom) and the appropriate depth is roughly around your elbow.
4. Adjust the bottle position in your hand so that the bottle is now parallel to lake surface and lake bottom, facing forward and **collect sample by sweeping the bottle forward** (forward, not up). This directional motion is important so that the water being collected in the bottle/jar does not pass over your hand. Collect water from that 22 – 30 cm. depth and then bring bottle to surface.
5. Empty it slightly (if it is full to the brim) and then recap bottle.
6. Store in the cooler chest.
7. **re quality control sample (lab and field duplicates).** Quality assurance is necessary to validate that the sampling and processing protocols have been followed appropriately. It is very important that these procedures are followed in order to ensure high quality results ...

If we are running duplicates (field and lab) on your site, there will be a large sampling jar, clearly marked, as well as a smaller one. Using the large jar, take your sample as per the steps outlined above. As soon as the sample is obtained, recap the jar (without touching interior of lid or jar) and shake it two or three times to ensure a uniform distribution of the discreet bacteria in the water sample. Immediately transfer some of the sample to the smaller jar. Cap both jars and store both jars. The contents of the

small jar are the sample, part of the remaining content of the large jar becomes the field duplicate and the balance of water in the large jar is sent for a quality control test at the Central Ontario Analytical Laboratory in Orillia.

The last part of quality assurance is distilled water. After the site sample and field duplicate have been collected, open the distilled water jug and fill the collection jar marked Distilled Water. Cap the glass bottle and place it in the cooler with the ice pack. Distilled water is, or should be, free of coliforms and e coli, and running a distilled water sample through our process (sterilized jars, sampling volunteers, Deb working the coliplates) is an excellent test of the scientific rigour of our program.

### Near shore Phosphorus testing:

*sample collected 22 – 30 cm. below the surface in water that is 1 m. in depth*

There are always a test tube **and** a PET jar associated with each phosphorus site (and sometimes extra test tubes for quality assurance purposes). The PET jar is used to actually collect the sample, which is then transferred to the test tube(s).

1. Carefully and correctly assemble the jars required for the specific site (all should be named and number coded)
2. Remove the top from the PET jar without touching the inside of top or jar and place in a flat, stable place.
3. **Rinse the jar in surface water at site.**
4. Rinse the filter (plastic funnel and filter cloth) in surface site water (filter stored in freezer bag.)
5. Grip the bottle at the base and plunge it into the water in a downward motion to the a depth of 22 – 30 cm. ( 9 – 15 in). The bottle goes in **upside down** (open end to lake bottom) and the appropriate depth is roughly around your elbow.
6. Adjust the bottle position in your hand so that the bottle is now parallel to lake surface and lake bottom, facing forward and **collect sample by sweeping the bottle forward** (forward, not up). This directional motion is important so that the water being collected in the bottle/jar does not pass over your hand. Collect water from that 22 – 30 cm. depth and then bring bottle to surface.
7. Take the top off the test tube, being careful not to touch the inside of the top or the test tube interior.
8. Gently swirl the water in the PET jar (don't spill it!) and then filter the water from the PET jar into the test tube using the filter (funnel plus filter cloth) provided. Fill the test tube to the line marked near the top of the test tube (want a tiny bit of air space in the tube for the lab to add some material.) Be prepared ... the filter cloth is a pain in the neck but it is important to filter out zooplankton which can distort phosphorus readings.
9. Cap tightly – both test tube and PET jar – and put both in the cooler.

**Note: be careful with the filters ...** they are light and blow away easily and it is also easy to lose/damage the filter cloths. **There is one filter per sampler for the entire summer!**

## **Deep Water Phosphorus Testing**

*sample is collected 10 – 15 m.(metres, not centimeters) below the surface in deep water*

While the process of collecting and filtering the sample is the same as that for near shore phosphorus, the sample is collected from further down in the water column. The process is as follows:

1. Attach the rope to the Secchi disc and measure the secchi depth by lowering the disc over the side of the boat until it disappears from view. It may take a bit of playing with it to verify when it actually disappears. Haul it up until you see it again and then slowly lower it. ( Know that in 8 years of doing this, I have NEVER had a secchi reading anywhere on Lake of Bays of less than 4.5 metres, and have occasionally had them up to 8 metres.) As you pull the disc back to the surface, count the number of metres (the rope is calibrated in 1 metre intervals.) Record this number. Redo to double check.
2. Record the colour of the water (orangey brown, bluey-green, etc.)
3. Attach the calibrated rope to the container for the secchi collection jar.
4. Rinse the collection jar in surface site water.
5. Lower the bottle (now in the weighted container to a distance that is **2 X** the secchi depth you observed and recorded above (the sample is being collected at a level to which light penetrates and given the refraction of light, that distance is 2 X the depth at which you could last see the disc.) The bottle should be lowered in a quick, smooth, but controlled motion (Don't let it free fall.)
6. Pull the container and collection jar back to the surface at a steady pace.
7. Use this water to rinse and fill the PET jar.
8. Swirl the water in the PET jar and then pour into the test tube **through the filter**. Fill test tube to the indicated line (just shy of full.)
9. Cap and place test tube and PET jar in cooler.

## **Re quality assurance for phosphorus ... near shore and deep water:**

Quality assurance is necessary to validate that the sampling and processing protocols have been followed appropriately. It is very important that these procedures are followed in order to ensure high quality results ...

1. If we are running phosphorus duplicates on your site, there will be an extra test tube, clearly marked as the field duplicate. Simply fill that second test tube in the same manner as the first, taking the time to gently swirl the contents of the PET jar before pouring water into the second test tube through the funnel and filter cloth. Cap test tubes and PET jar and store in cooler.
2. The last part of quality assurance is distilled water. After the site sample and field duplicate have been collected, open the distilled water jug and fill the clearly marked test tube to the line (7/8<sup>th</sup> full). Cap and store with rest of samples from that particular site.
